

Angular a Web Framework

Web Framework: Crafted for Users, Powered by Google

"Angular is a web framework that empowers developers to build fast, reliable applications that users love."

– <https://angular.dev/>

We have developed an Angular application in previous session, where Parent to Child and Child to Parent communication was done with following steps:

- Parent contains employee data.
- Parent sends employee data to Child using @Input().
- Child displays the employee.
- Child has a Promote button.
- When clicked, Child sends an event to Parent using @Output().
- Parent receives the event and updates the employee designation and salary.

Now we will extend the same application to understand Sibling → Sibling communication in Angular with Employee Management scenario.

The key concept is:

- Sibling components should not directly communicate with each other.
- Their common parent acts as the communication bridge.

We can build this scenario, imagine an Employee Management application.

- Employee List displays all employees.
- User clicks an employee in the list.
- EmployeeListComponent sends the selected employee to the Parent(empdashboard).
- Parent passes the selected employee to EmployeeDetailsComponent.
- Employee Details displays the selected employee details.

So, the communication flow is:

EmployeeList → Employee selected → EmpDashboard → Selected Employee → EmployeeDetails

Connecting parts, sharing data, building apps.
