

Angular a Web Framework

Web Framework: Crafted for Users, Powered by Google

Day 27 – Working With Auth

Authentication and authorization are important for creating secure and user-friendly applications in Angular. Build an Angular project featured user authentication & authorization flow, protected routes, etc. Just to keep things simple consider login should work as described:

1. Admin/User Oriented app, only authenticated users can go in. So, login should appear first and then based on Authentication-Authorization navigating to other components. We mostly manage using routing.
2. Use Hard Coded / Static username and password.
3. Create a component that will appear only after logging in. Name it layout.
4. Create Nav bar using proper styles.
5. Once logged in the Logged User Name should be displayed with Hello....
6. Add LogOff functionality also.
